# **CS 315 - Theory of Automata**

# **Final Project**

**Deadline:** Sunday 18th April 2021 (11:55 pm)

One of the most common thoughts that any programmer has is "Why does this language have to be written like this?". You might question why C++ uses semicolons when a full stop is more intuitive. Perhaps you want a language where you can use Urdu phrases, for example karo (a < 10) jabtak ... to emulate a do-while loop. Or you might want to create an esoteric language to compete with whitespace (Figure. 1 shows how hello world is written in whitespace in a language made on *April 1st*, 2003). Maybe, you wish to attain a better understanding of how an interpreter operates. The solution to all these problems is simple: **Make your own programming language.** 

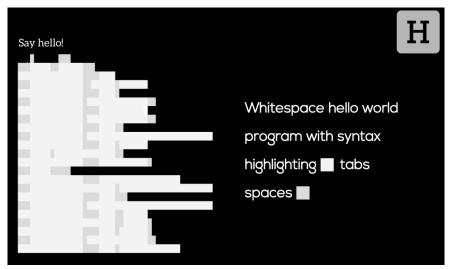

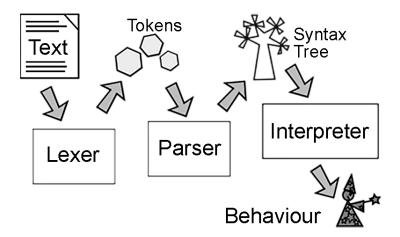

Fig. 1. Source

That is exactly what we are going to do in this project. We will give you the opportunity to design your own language which is filled with features that you want and has the syntax that you want. You want a language whose syntax is a combination of various languages? That's up to you. You want to come up with a brand new syntax? That's up to you. That language is called YAPL (Yet Another Programming Language) and this project affords each one of you the opportunity to design your own YAPL. After finishing this project, you should be able to use your language in other CS courses;)

Now you might be wondering "How do I design a YAPL?". The answer to this is three different components: **lexer**, **parser** and **interpreter**. First of all, you need to make a lexer. A lexer basically takes a sequence of characters (ex. Your high level code) as input and outputs a sequence of tokens. Next up is the parser. The parser takes these tokens and outputs a parse tree where each branch is filled with your expressions or statements. Finally, you have the interpreter which goes through each branch and evaluates it.

#### **Tool Introduction:**

PLY consists of two separate modules; **lex.py** and **yacc.py**, both of which are found in the Python package called ply. (Use pip to install it!) You can also use <u>SLY</u> optionally which originates from PLY by the same creator and offers a more modernized syntax.

The *lex.py* module is used to break input text into a collection of tokens specified by a collection of regular expression rules.

yacc.py module is used to recognize language syntax that has been specified in the form of a context free grammar. yacc.py provides most of the features you expect including extensive error checking, grammar validation, support for empty productions, error tokens, and ambiguity resolution via precedence rules.

The two tools are meant to work together. Specifically, lex.py provides an external interface in the form of a token() function that returns the next valid token on the input stream. yacc.py calls this repeatedly to retrieve tokens and invoke grammar rules.

#### **Rules and Guidelines:**

- Implement a **lexer**, **parser**, and **interpreter** of your YAPL in the PLY/SLY library and execute the test cases provided to you.
- Your implementation must be generic enough to cater to all possible scenarios.
- The core project is divided up into four parts (the divisions are explained under Task Breakdown) - Core Fundamentals, Loops, Data Structures and Functions. For the Loops and Data Structures sections you only have to implement one of the two constructs given based on the parity of your roll number (even/odd).
- You have been provided test cases at the end of this document that will be used to evaluate your project. Therefore, you are supposed to submit .txt files for each test case (for the constructs that you have been allotted) as explained in the submission format at the end of the document. However, these test cases would only account for half of the marks for each component. The other half of the marks would be evaluated using hidden test cases that would be revealed after the project deadline. Details of the hidden test cases would be provided later on Slack and LMS.
- Your language should be able to handle any code which uses the functionalities specified in the given tasks, since you will be marked on new test cases after submission.
- You should implement maximum error handling that a language provides.
- Late submission (1 day late) with 10% deduction is allowed until Monday, 19<sup>th</sup>
   April 2021. No extensions will be granted. Timely uploading to LMS is YOUR
   RESPONSIBILITY. Do not wait for the last moment. We will only accept LMS
   submitted assignments and directly run the test cases on our machine.
- Plagiarism will be detected using multiple tools and forwarded directly to the DC.

## Tips:

<u>Disclaimer: This is all up to you! These tips are completely optional and just for guidance.</u>

- It will be easier if you use a stricter syntax, such as semicolons for the end of a statement and braces to limit the scope of blocks instead of indentation.
- Save error handling for the end, focus on the core functionality first!
- Refer to the test cases for clearing any confusions regarding the task descriptions.

# Tasks Breakdown: (Total Marks: 30) Core Fundamentals: (Marks: 11)

Variables (2):

- a. Declaration, assignment, access
- b. Static-typing (types restricted to: int, float, char, string, bool)
- c. Initialisation and declaration of a variable with the name of a pre-existing variable should generate an error.

# Expressions (3):

- a. Numerical Operators: (binary + , , / , \* , ^, % , and unary ++, --)
- b. Logical Operators (<, >, <=,>=, !=, ==, NOT, AND, OR)
- c. Nested Parentheses
- d. String Concatenation
- e. Type (e.g. for String + Int) and division by 0 errors

#### Standard Output (1)

- a. Single object is printed with a line break.
- b. Multiple objects separated by a delimiter (e.g. comma as in Python) are printed with spaces in between and a line break at the end.

# If-elseif-else statements (5):

- a. Can be nested
- b. Can be an if statement, or just an if-elseif-elseif-...else or if-elseif or an if-else

Loops: (Marks: 8)

# Depending on whether your roll number is even/odd.

For example, if your roll number is *22100150*, then you must attempt *Do-While Loops*. If your roll number is *21100131*, then you must attempt *For Loops*.

# [EVEN] Do-While Loops:

- a. Can be nested
- b. Can support initialization, condition or update statements of any variable type.

# [ODD] For Loops:

- a. Can be nested
- b. Can support initialization, condition or update statements of any variable type.

Data Structures: (Marks: 6)

# Depending on whether your roll number is even/odd.

#### [EVEN] List:

- a. Declaration, assignment, access
- b. IndexOutofBounds error when access is outside the list-size.
- c. list.pop(index of item to remove) // list.pop(0) removes the head of the list and returns it
- d. list.push(value) // appends the value at the end of the list
- e. list.index(index) // returns the value at that index
- f. list.slice(start, end) // end index excluded e.g. [6, 3, 1, 5, 2].slice(1, 4) returns [3, 1, 5]

# [ODD] Structs:

- a. Define a struct
- b. Create an object with the defined struct type
- c. Access the variables/attributes declared inside the struct and assign values
- d. AttributeError when a non-existing attribute is accessed

Functions: (Marks: 5)

Functions & Recursion:

- a. Definition and scope of local variables
- b. Supports multiple parameters of the primitive types
- c. Function calls and returning values
- d. Recursion

# **Required Test Cases with Outputs:**

All the given test cases with outputs have been provided in a **pseudo-code-like syntax** for your ease of understanding. Therefore, you <u>do not</u> need to abide by or stay limited to any of the given keywords or tokens in general as long as it is understandable, but just keep in mind the features of every construct shown. Your outputs should exactly match the ones provided.

# **Standard Output:**

```
PRINT("STANDARD OUTPUT")
PRINT(5.4, True, 2)

STANDARD OUTPUT
5.4 TRUE 2
```

#### Variables:

```
STRING a = "start"

INT b = 1

DOUBLE c = 2.5

BOOL d = FALSE

INT e = 0

STRING f = "end"

PRINT(a)

PRINT(b,c)

PRINT(d,e)

PRINT(d,e)

PRINT(f)

INT e = 5
```

# **Expressions:**

```
STRING mystring = ("theory" + " of ") + "automata"
                                                                theory of automata
INT a = 1
                                                                -1
INT b = 4
                                                                TRUE
b++
                                                                TypeError
PRINT(mystring)
DOUBLE c = (1.5+0.5+2)
DOUBLE determinant = b ^ 2 - 4 * a * c
DOUBLE quadratic root1 = (-b + determinant^{(1/2)}) / (2.0*a)
PRINT(quadratic root1)
BOOL d = FALSE
PRINT(NOT TRUE == (NOT (NOT d)) AND (TRUE != 0))
PRINT(4 + "A")
PRINT("Hi")
```

#### If-elseif-else:

```
BOOL isRaining = FALSE
                                                                 Wear down jacket
BOOL is Snowing = TRUE
INT temperature = 0
IF (isRaining == TRUE)
      IF(temperature > 45) {
            PRINT("Wear lightweight raincoat")
      ELSEIF(temperature == 45) {
            PRINT("Wear lightweight raincoat")
      ELSE {
            PRINT("Wear fleece and raincoat")
ELSE IF (isSnowing != FALSE)
      IF(temperature > 20) {
            PRINT("Wear soft shell jacket")
      ELSEIF (temperature >= 0) {
            PRINT("Wear down jacket")
      }
      ELSE {
            PRINT("Wear base layers and down jacket")
      }
ELSE {
      print("It is hard to come up with interesting examples")
```

## **Do-while Loops:**

```
INT i=0
                                                                                            , 0 , 1 )
, 1 , 0 )
, 1 , 1 )
, 0 , 0 )
, 0 , 1 )
DO {
        INT j=0
        DO
                                                                                           0
1
1
        {
                 INT k=0
                                                                                                   , 0
                                                                                                 1
                 DO
                         PRINT("(", i, ",", j, ",", k, ")")
                         k++
                 } WHILE (k<2)</pre>
                 j++
        } WHILE (j<2)
        i++
} WHILE (i<2)
```

#### For Loops:

#### Lists:

```
LIST A = [1,2,3,4,5,6]

LIST B = []

PRINT(B)

PRINT(A.slice(0, 2))

B.push("Get Ready!")

B.push("Done!")

PRINT(B.index(1))

STRING C = "Well " + B.pop(1)

PRINT(C)

PRINT(A[7])
```

#### **Structs:**

```
STRUCT BookStruct {
                                                            The Theory of Computation
   STRING title
                                                            Michael Sipser
   STRING author
                                                            Theory of Computation
   STRING subject
                                                            4531<u>5</u>
   INT book id
                                                            Race Against the Machine
};
                                                            Andrew McAfee
BookStruct Book1
                                                            Digital Technology
BookStruct Book2
                                                            92315
                                                            AttributeError
Book1.title = "The Theory of Computation"
Book1.author = "Michael Sipser"
Book1.subject = "Theory of Computation"
Book1.book_id = 45315
Book2.title = "Race Against the Machine"
Book2.author = "Andrew McAfee"
Book2.subject = "Digital Technology"
Book2.book id = 92315
PRINT(Book1.title)
PRINT(Book1.author)
PRINT(Book1.subject)
```

```
PRINT(Book1.book_id)
PRINT("")
PRINT(Book2.title)
PRINT(Book2.author)
PRINT(Book2.subject)
PRINT(Book2.book_id)
PRINT(Book2.publisher)
```

#### **Functions & Recursion:**

```
FUNCTION fib(INT n){
    IF ((n == 1) OR (n==0)) {
        RETURN n
    }

    RETURN fib(n-1) + fib(n-2)
}

PRINT(fib(9))
```

#### **Submission Format:**

Create a folder inside your main directory (where your .py files are located)
called "test\_cases" and insert ".txt" files following the names below for the
given test cases of the constructs allotted to you.

```
standard_output.txt
variables.txt
expressions.txt
if_else.txt
do_while_loops.txt
for_loops.txt
lists.txt
structs.txt
functions_recursion.txt
```

 Your <u>lexer</u>, <u>parser</u> and <u>interpreter files</u> <u>must</u> stay as <u>separate</u> .py <u>files</u> as shown below. For example, a typical file hierarchy for a specific student would be: test\_cases

```
standard_output.txt
variables.txt
expressions.txt
if_else.txt
for_loops.txt
lists.txt
functions_recursion.txt
yapl_lexer.py
yapl_parser.py
yapl_interpreter.py
[any extra project files as required]
```

• Finally, your **yapl\_interpreter.py** file requires the user to add the *txt* file's name to be read from the test\_case folder as an additional <u>command line</u> <u>parameter</u> and executes that test case by reading that file. Example prompt:

```
>> python yapl_interpreter.py standard_output.txt
Welcome to the MyYAPL Interpreter!
Output:
STANDARD OUTPUT
5.4 TRUE 2
```

 Zip the python files and the test\_case folder together shown above with the naming convention <u>rollnumber project.zip</u> and upload on LMS before the given deadline.
